SQL

Fall 2019

Introduction

SQL is an example of a declarative programming language. Statements do not describe computations directly, but instead describe the desired result of some computation. It is the role of the query interpreter of the database system to plan and perform a computational process to produce such a result.

In SQL, data is organized into tables. A table has a fixed number of named columns. A row of the table represents a single data record and has one value for each column. For example, we have a table named records that stores information about the employees at a small company¹. Each of the eight rows represents an employee.

records					
Name	Division	Title	Salary	Supervisor	
Ben Bitdiddle	Computer	Wizard	60000	Oliver Warbucks	
Alyssa P Hacker	Computer	Programmer	40000	Ben Bitdiddle	
Cy D Fect	Computer	Programmer	35000	Ben Bitdiddle	
Lem E Tweakit	Computer	Technician	25000	Ben Bitdiddle	
Louis Reasoner	Computer	Programmer Trainee	30000	Alyssa P Hacker	
Oliver Warbucks	Administration	Big Wheel	150000	Oliver Warbucks	
Eben Scrooge	Accounting	Chief Accountant	75000	Oliver Warbucks	
Robert Cratchet	Accounting	Scrivener	18000	Eben Scrooge	

Creating Tables

We can use a SELECT statement to create tables. The following statement creates a table with a single row, with columns named "first" and "last":

```
sqlite> SELECT "Ben" AS first, "Bitdiddle" AS last;
Ben|Bitdiddle
```

Given two tables with the same number of columns, we can combine their rows into a larger table with UNION:

```
sqlite> SELECT "Ben" AS first, "Bitdiddle" AS last UNION
   ...> SELECT "Louis",
                                "Reasoner";
Ben|Bitdiddle
Louis|Reasoner
```

¹Example adapted from Structure and Interpretation of Computer Programs

To save a table, use CREATE TABLE and a name. Here we're going to create the table of employees from the previous section and assign it to the name records:

```
sqlite> CREATE TABLE records AS
...> SELECT "Ben Bitdiddle" AS name, "Computer" AS division,
...> "Wizard" AS title, 60000 AS salary,
...> "Oliver Warbucks" AS supervisor UNION
...> SELECT "Alyssa P Hacker", "Computer",
...> "Programmer", 40000, "Ben Bitdiddle" UNION ...;
```

We can SELECT specific values from an existing table using a FROM clause. This query creates a table with two columns, with a row for each row in the records table:

```
sqlite> SELECT name, division FROM records;
Alyssa P Hacker|Computer
Ben Bitdiddle|Computer
Cy D Fect|Computer
Eben Scrooge|Accounting
Lem E Tweakit|Computer
Louis Reasoner|Computer
Oliver Warbucks|Administration
Robert Cratchet|Accounting
```

The special syntax SELECT * will select all columns from a table. It's an easy way to print the contents of a table.

```
sqlite> SELECT * FROM records;
Alyssa P Hacker|Computer|Programmer|40000|Ben Bitdiddle
Ben Bitdiddle|Computer|Wizard|60000|Oliver Warbucks
Cy D Fect|Computer|Programmer|35000|Ben Bitdiddle
Eben Scrooge|Accounting|Chief Accountant|75000|Oliver Warbucks
Lem E Tweakit|Computer|Technician|25000|Ben Bitdiddle
Louis Reasoner|Computer|Programmer Trainee|30000|Alyssa P Hacker
Oliver Warbucks|Administration|Big Wheel|150000|Oliver Warbucks
Robert Cratchet|Accounting|Scrivener|18000|Eben Scrooge
```

We can choose which columns to show in the first part of the SELECT, we can filter out rows using a WHERE clause, and sort the resulting rows with an ORDER BY clause. In general the syntax is:

```
SELECT [columns] FROM [tables]
WHERE [condition] ORDER BY [criteria];
```

For instance, the following statement lists all information about employees with the "Programmer" title.

```
sqlite> SELECT * FROM records WHERE title = "Programmer";
Alyssa P Hacker|Computer|Programmer|40000|Ben Bitdiddle
Cy D Fect|Computer|Programmer|35000|Ben Bitdiddle
```

The following statement lists the names and salaries of each employee under the accounting division, sorted in **descending** order by their salaries.

sqlite> SELECT name, salary FROM records
 ...> WHERE division = "Accounting" ORDER BY -salary;
Eben Scrooge|75000
Robert Cratchet|18000

Note that all valid SQL statements must be terminated by a semicolon (;). Additionally, you can split up your statement over many lines and add as much whitespace as you want, much like Scheme. But keep in mind that having consistent indentation and line breaking does make your code a lot more readable to others (and your future self)!

Questions

Our tables:

records: Name Division Title Salary Supervisor

- 2.1 Write a query that outputs the names of employees that Oliver Warbucks directly supervises.
- 2.2 Write a query that outputs all information about employees that supervise themselves.
- 2.3 Write a query that outputs the names of all employees with salary greater than 50,000 in alphabetical order.

3 Joins

Suppose we have another table meetings which records the divisional meetings.

meetings				
Division	Day	\mathbf{Time}		
Accounting	Monday	9am		
Computer	Wednesday	$4\mathrm{pm}$		
Administration	Monday	11am		
Administration	Wednesday	$4\mathrm{pm}$		

Data are combined by joining multiple tables together into one, a fundamental operation in database systems. There are many methods of joining, all closely related, but we will focus on just one method (the inner join) in this class.

When tables are joined, the resulting table contains a new row for each combination of rows in the input tables. If two tables are joined and the left table has m rows and the right table has n rows, then the joined table will have mn rows. Joins are expressed in SQL by separating table names by commas in the FROM clause of a SELECT statement.

```
sqlite> SELECT name, day FROM records, meetings;
Ben Bitdiddle | Monday
Ben Bitdiddle | Wednesday
...
Alyssa P Hacker | Monday
```

Tables may have overlapping column names, and so we need a method for disambiguating column names by table. A table may also be joined with itself, and so we need a method for disambiguating tables. To do so, SQL allows us to give aliases to tables within a FROM clause using the keyword AS and to refer to a column within a particular table using a dot expression. In the example below we find the name and title of Louis Reasoner's supervisor.

```
sqlite> SELECT b.name, b.title FROM records AS a, records AS b
...> WHERE a.name = "Louis Reasoner" AND
...> a.supervisor = b.name;
Alyssa P Hacker | Programmer
```

Questions

Our tables:

```
records: Name Division Title Salary Supervisor

meetings: Division Day Time
```

3.1 Write a query that outputs the meeting days and times of all employees directly supervised by Oliver Warbucks.

3.2 Write a query that outputs the names of employees whose supervisor is in a different division.

3.4 (Extra question) Will the statement above filter out all redundant output in all cases? Why or why not?

4 Aggregation

So far, we have joined and manipulated individual rows using SELECT statements. But we can also perform aggregation operations over multiple rows with the same SELECT statements.

We can use the MAX, MIN, COUNT, and SUM functions to retrieve more information from our initial tables.

If we wanted to find the name and salary of the employee who makes the most money, we might say

```
sqlite> SELECT name, MAX(salary) FROM records;
Oliver Warbucks|150000
```

Using the special COUNT(*) syntax, we can count the number of rows in our table to see the number of employees at the company.

```
sqlite> SELECT COUNT(*) from RECORDS;
9
```

These commands can be performed on specific sets of rows in our table by using the GROUP BY [column name] clause. This clause takes all of the rows that have the same value in column name and groups them together.

We can find the miniumum salary earned in each division of the company.

```
sqlite> SELECT division, MIN(salary) FROM records GROUP BY division;
Computer|25000
Administration|25000
Accounting|18000
```

These groupings can be additionally filtered by the HAVING clause. In contrast to the WHERE clause, which filters out rows, the HAVING clause filters out entire groups.

To find all titles that are held by more than one person, we say

sqlite> SELECT title FROM records GROUP BY title HAVING count(*) > 1; Programmer

Questions

Our tables:

records: Name Division Title Salary Supervisor

meetings: Division Day Time

- 4.1 Write a query that outputs each supervisor and the sum of salaries of all the employees they supervise.
- 4.2 Write a query that outputs the days of the week for which fewer than 5 employees have a meeting. You may assume no department has more than one meeting on a given day.

4.3 Write a query that outputs all divisions for which there is more than one employee, and all pairs of employees within that division have a salary less than 100,000.

5 Extra Questions

Use the following table called courses for the questions below:

courses					
Professor	\mathbf{Course}	Semester			
Dan Garcia	CS 61C	Sp19			
John DeNero	CS~61A	Fa18			
Dan Garcia	CS 10	Fa18			
Josh Hug	CS~61B	Sp18			
John DeNero	CS~61A	Sp18			
John DeNero	CS~61A	Fa17			
Paul Hilfinger	CS~61A	Fa17			
Paul Hilfinger	CS~61A	Sp17			
John DeNero	Data 8	Sp17			
Josh Hug	CS~61B	Sp17			
Satish Rao	CS70	Sp17			
Nicholas Weaver	CS~61C	Sp17			
Gerald Friedland	CS~61C	Sp17			
:	:	÷			

5.1 Create a table called num_taught that contains three columns: professor, the course they taught, and the number of times they taught each course.

5.2 Write a query that outputs two professors and a course if they have taught that course the same number of times. You may use the num_taught table you created in the previous question.

5.3 Write a query that outputs two professors if they co-taught (taught the same course at the same time) the same course more than once.
